Let us denote by E(n) the isometry group $Isom(\mathbb{R}^n) = O(n) \ltimes \mathbb{R}^n$ of the *n*-dimensional Euclidean space.

Definition

A crystallographic group of dimension n is a cocompact and discrete subgroup of E(n).

Example

1. Z^n 2. If $(B, \begin{pmatrix} 1/2 \\ 0 \end{pmatrix}), (I, \begin{pmatrix} 0 \\ 1 \end{pmatrix}) \in E(2)$, where $B = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$, then the group $\Gamma \subset E(2)$ generated by the above elements is a crystallographic group of dimension 2.

crystallographic group of dimension 2.

The first part of the eighteenth Hilbert problem was about the description of discrete and cocompact groups of isometries of \mathbb{R}^n .

The answer for the above Hilbert problem was given by the German mathematician L. Bieberbach in 1913.

Theorem

(Bieberbach) 1. If $\Gamma \subset E(n)$ is a crystallographic group then the set of translations $\Gamma \cap (I \times \mathbb{R}^n)$ is a torsion free and finitely generated abelian group of rank n, and is a maximal abelian and normal subgroup of finite index.

2. For any natural number n, there are only a finite number of isomorphism classes of crystallographic groups of dimension n.

3. Two crystallographic groups of dimension n are isomorphic if and only if they are conjugate in the group $A(n) = GL(n, \mathbb{R}) \ltimes \mathbb{R}^n$.

A flat manifold M^n of dimension n is a compact connected Riemannian manifold without boundary with sectional curvature equal to zero.

Example

1. torus
$$\mathbb{R}^n/\mathbb{Z}^n \simeq \underbrace{S^1 \times S^1 \times \cdots \times S^1}_{}$$

2. $\mathbb{R}^n/\Gamma,$ where $\Gamma\subset E(n)$ is a torsion free crystallographic group

Remark

Any flat manifold $M^n \simeq \mathbb{R}^n / \Gamma$, where $\Gamma = \pi_1(M^n)$. Γ is a torsion free crystallographic group of rank n.

イロン イヨン イヨン イヨ

From now, all crystallographic groups have a trivial center. It is easy to see, that in this case $(\mathbb{Z}^n)^G = 0$ and $Inn(\Gamma) = \Gamma$. We have a restriction homomorphism $F : Aut(\Gamma) \to Aut(\mathbb{Z}^n)$. In 1973 L. Charlap and A.T.Vasquez proved that the kernel F_0 of F is isomorphic to $Z^1(G, \mathbb{Z}^n)$ and the following diagram has exact rows and columns. This is our main technical tool.

We shall need a few lemmas.

Lemma Aut(Γ) is a crystallographic group if and only if Out(Γ) is a finite group.

Proof: We start with an observation that $Z^1(G, \mathbb{Z}^n)$ is a free abelian group of rank *n* which is a faithful N_α module. First, assume that $Aut(\Gamma)$ is a crystallographic group with the maximal abelian subgroup *M*. From Bieberbach's theorems, *M* is the unique normal maximal abelian subgroup of $Aut(\Gamma)$. Hence, $M = Z^1(G, \mathbb{Z}^n)$, and $Out(\Gamma)$ is a finite group. The reverse implication is obvious.

ightarrow} Aut(H)$$

and

$$N_{GL(n,\mathbb{Z})}(G)/C_{GL(n,\mathbb{Z})}(G) \stackrel{\overline{\phi}}{\rightarrow} Aut(G),$$

where $\overline{\phi}$ is induced by $\phi(s)(g) = sgs^{-1}, g \in G, s \in GL(n, \mathbb{Z})$. Since $C_{GL(n,\mathbb{Z})}(G) \subset C_{GL(n,\mathbb{Z})}(H)$, our Lemma is proved.

イロン イヨン イヨン イヨン

Let G, H be finite groups and $H \subset G \subset GL(n,\mathbb{Z})$. If the group $N_{GL(n,\mathbb{Z})}(H)$ is finite, then $N_{GL(n,\mathbb{Z})}(G)$ is finite.

Proof: From the assumption, Aut(H) and Aut(G) are finite and we have monomorphisms:

$$N_{GL(n,\mathbb{Z})}(H)/C_{GL(n,\mathbb{Z})}(H) \stackrel{ar{\phi}}{
ightarrow} Aut(H)$$

and

$$N_{GL(n,\mathbb{Z})}(G)/C_{GL(n,\mathbb{Z})}(G) \stackrel{\overline{\phi}}{\rightarrow} Aut(G),$$

where $\overline{\phi}$ is induced by $\phi(s)(g) = sgs^{-1}, g \in G, s \in GL(n, \mathbb{Z})$. Since $C_{GL(n,\mathbb{Z})}(G) \subset C_{GL(n,\mathbb{Z})}(H)$, our Lemma is proved.

Let Γ be a crystallographic group with a holonomy group G of dimension n. Assume that the group $H^1(G, \mathbb{Z}^n) = \{e\}$, and the group $Out(\Gamma)$ is finite.

Inductively, put $\Gamma_0 = \Gamma$ and $\Gamma_{i+1} = A(\Gamma_i)$, for $i \ge 0$.

Lemma

$\exists N \text{ such that } \Gamma_{N+1} = \Gamma_N.$

Proof: We start from observations that for i > 0, Γ_i is a crystallographic group, $Z(\Gamma_i) = \{e\}$ and $M_0 = M_i$, where $M_i = A^0(\Gamma_{i-1}) \subset \Gamma_i$ is the maximal abelian normal subgroup (a subgroup of translations). Let $G_i = \Gamma_i/M_i$. From definition we can consider (G_i) as a nondecreasing sequence of finite subgroups of $GL(n, \mathbb{Z})$. From Bieberbach theorems and from the diagram, there is only a finite number of possibilties for G_i . Hence $\exists N \in \mathbb{N}$ such that $\forall_{i>N}$ $G_i = G_N$. This finishes the proof.

Example

Let $\Gamma_2 = G_2 \ltimes \mathbb{Z}^3$ be the crystallographic group of dimension 3, with holonomy group $G_2 = S_4 \times \mathbb{Z}_2$ generated by matrices

$$\begin{bmatrix} 0 & 1 & 0 \\ 0 & -1 & -1 \\ 1 & 1 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 & 1 \\ 0 & -1 & -1 \\ -1 & 0 & 1 \end{bmatrix}$$

Here S_4 denotes the symmetric group on four letters. For i = 1, 2 we have

$$N_{GL(n_i,\mathbb{Z})}(G_i)=G_i$$
 and $H^1(G_i,\mathbb{Z}^{n_i})=0,$

where n_i is the rank of Γ_i . Hence $A(\Gamma_i) = \Gamma_i$, and $Out(\Gamma_i) = \{e\}$, for i = 1, 2.

Now we are ready to finish the proof of Theorem. The cases n = 2, 3 are done in the above examples. Assume $n \ge 4$. Assume Γ' is a crystallographic group given by a short exact sequence

 $0\to\mathbb{Z}^n\to\Gamma'\to S_{n+1}\to 0$

with a holonomy representation s.t. $H^1(S_{n+1}, \mathbb{Z}^n) = 0$. (It is enough to consider S_{n+1} modul \mathbb{Z}^{n+1} with permutation action on the standard basis $e_1, e_2, ..., e_{n+1}$ divided by a submodule of rank one generated by $\{e_1 + e_2 + ... + e_{n+1}\}$.) Hence, Γ' satisfies the assumption of the last Lemma and the sequence $\Gamma_0 = \Gamma'$, $\Gamma_{i+1} = A(\Gamma_i)$ stabilizes, i.e., $\exists N$ such that $\forall_{i>N}$ $\Gamma_i = \Gamma_N$. Finally, $Out(\Gamma_N) = \{e\}$ and $Z(\Gamma_N) = \{e\}$.

・ロン ・四 と ・ 回 と ・ 回 と

1. Find a new example of a torsion free crystallographic group Γ with trivial center and trivial outer automorphism group.

2. For any finite group G find an example of (torsion free) crystallographic group Γ such that $Out(\Gamma) = G$.

3. Let G a finite group. Are there exist a natural number n and a subgroup $A \subset S_n$ of the permutation group S_n , such that

$$N_G(A)/A \simeq G?$$

Here $N_G(A)$ is a normalizer of the subgroup A in S_n .

Thank You
